CONTENTS.

INTRODUCTION.

The number of investigators in the total metabolism of matter and transformations of energy in man, animals, and plants is rapidly increasing, as well as the number of individuals (principally clinicians) who are making practical applications of the methods used and the results obtained in these fields. The apparatus used and the methods of calculation applied necessitate frequently the use of tables and conversion factors. The tables most used are those in connection with the measurements of respiratory exchange, the reduction of gas volumes to standard conditions, computation of heat, and the standards of normal metabolism. At present these are published in various places and no adequate compilation of them exists.

The purpose of this publication is to make available to investigators the majority of tables and conversion factors needed in calculations of results from measurements obtained by the several types of respiratory exchange apparatus, particularly the Regnault-Reiset and the combination of spirometer, valves, and breathing appliance, and to make available the standards of normal metabolism.

The method of presentation is as follows: A section giving the method of construction and calculation of the tables and their application is followed by the section giving the tables themselves. The last part gives formulas and conversion factors which may be of use.

The tables and factors have been collected from various sources and principally from Smithsonian Physical Tables, 1896, 1920; Smithsonian Geographical Tables, 1918; Landolt-Börnstein Physikalisch-chemische Tabellen, 1905; Jeleniks Psychrometer-Tafeln, 1911; articles published in the Archives of Internal Medicine by workers of the Russell Sage Institute of Pathology and the Cornell Medical School; publications of the Carnegie Institution of Washington; Armsby's Principles of Animal Nutrition, 1906; and Joslin's Treatment of Diabetes Mellitus, 1917. Some of the tables have been computed by the staff of the Nutrition Laboratory.

This publication was prepared at the suggestion of Professor Francis G. Benedict, whose advice in the selection and ranges of the tables has been very helpful.

The calculation and preparation of the majority of the tables have been under the supervision of Mr. W. H. Leslie and their accuracy is due to his painstaking care. He was assisted by Miss Clara E. Borden, Miss Mary D. Finn, and Mrs. F. N. Horton. He

has also been helpful in the wording of headings and the section on description and uses of the tables.

Acknowledgment is made to Professor G. W. Pierce, of Harvard College, for his advice in the preparation of the tables of physical constants.

DESCRIPTION AND USE OF TABLES.

TABLE 1. *Conversion of seconds to decimal parts of a minute.*

This table is obtained by dividing the number of seconds by 60 and expressing the result to the nearest 0.01 minute. It is useful where time is observed in minutes and seconds and where it is necessary in computation to convert to minutes and decimal parts. The same table can be used to ascertain the decimal fraction of an hour corresponding to minutes.

TABLE 2. *Pressure of aqueous vapor at dry-bulb temperatures 15° to 25° C. for relative humidities between 30 and 75 per cent.*

This table gives the pressure of aqueous vapor in millimeters of mercury to 0.1 millimeter for temperatures of the dry-bulb ranging from 15° to 25° C. and of the wet-bulb from 8.0° to 21.9° C. It is mainly useful for obtaining from the readings of a wet-bulb and dry-bulb psychrometer the partial pressure due to water-vapor when the gas is neither saturated nor dry and it is desired to calculate the reduction of the volume to 760 millimeters dry. Its practical application is in connection with experiments with respiration chambers. The side argument is for the dry-thermometer readings to 0.1° C. and the top argument gives the readings of the wet thermometer to 0.1°.

TABLE 3. *Pressure of aqueous vapor at saturation.*

The table gives the pressure of water-vapor in 0.01 millimeter mercury at temperatures to 0.1° C., ranging from 10.0 to 36.9° C., when a gas is completely saturated. It is useful in calculating the reduction of gas volumes to 760 millimeters dry when they are observed under the conditions of complete saturation at any given temperature. In combination with table 2, relative humidities can be calculated (within 1 per cent) by dividing the millimeters pressure at the given wet-bulb and dry-bulb thermometer readings by the millimeters pressure for saturation at the temperature of the dry-bulb thermometer. The result multiplied by 100 will give percentage relative humidity. The top argument gives the 0.1°; the side argument 1.0°. The table is from Smithsonian Physical Tables, 1920, pp. 183, 184.

TABLE 4. *Millimeters to be subtracted from barometer (brass-scale) readings to reduce them to 0° C.*

The correction necessary to be applied to readings obtained from a barometer having a brass scale, in order to change them to a temperature of 0° C., is given to 0.01 millimeter mercury for temperatures ranging from 11.0° to 36.0° C. and for barometric pressures from 740 to 780 millimeters. The table is used in connection with calculations of reduction of gases to 760 millimeters, where a brass-scale barometer has been used. The top argument is pressure every 10 millimeters. The side argument is temperature every 0.5° C. It is from Landolt-Börnstein Physikalisch-chemische Tabellen, 1905, page 35.

TABLE 5. *Logarithms of $p/760$ for barometric pressures between 700.0 and 780.9 millimeters.*

This table is calculated by subtracting the logarithm of 760 from the logarithm of the barometric pressure corrected to 0° C. It is used in computing the reduction of gas volumes to a pressure of 760 millimeters, where p equals the observed pressure corrected to 0° C., by means of table 4.

TABLE 6. *Logarithms of $\frac{1}{1+0.00367\,t}$ for temperatures between 11.0° and 36.09° C.*

The table is calculated by computing the cologarithms for values of $1+0.00367\,t$, where t equals the temperature in degrees centigrade. It is used in calculating the reduction of gas volumes to 0° C. from observed temperature t. The top argument is from 0.00° to 0.09° C. The side argument is in tenths of a degree centigrade.

TABLE 7. *Logarithms for the reduction of saturated volumes to 0° C. dry and 760 millimeters pressure.* $\left(\frac{1}{1+0.00367\,t}\times\frac{p-e}{760}\right)$

t = temperature, p = barometric pressure corrected to 0° C., and e = pressure of aqueous vapor at t.

This table is calculated by subtracting the pressure of aqueous vapor (e) at t as found in table 3, page 30, from the barometer reading p corrected to 0° C. for scale correction. The logarithm of $p/760$ is then found in table 5, page 32, and added to the logarithm of $1/1+0.00367\,t$ as found in table 6, page 34. The table is useful for the calculation of reduction of gas volumes to 0° and 760 millimeters where the volumes are measured under conditions of atmospheric pressure, known temperature, and saturated with aqueous vapor such as expired air collected in a spirometer or passed through a wet-gas meter. The top argument gives the barometric pressure in millimeters. The side argument gives the temperature t to 0.1° C.

TABLE 8. *Factors for reduction of saturated volumes to* 0° *C. dry and* 760 *millimeters pressure.* $(1/1 + 0.00367\,t) \times (p - e/760)$ t = temperature, p = pressure, e = pressure of aqueous vapor at temperature t.

The table is calculated in the same manner as table 7, except that the factors themselves are used instead of the logarithms. The table was actually constructed by reading the antilogarithms of table 7. The top argument is in millimeters pressure—that is, the observed reading corrected for temperature. The side argument gives the temperature t to 0.1° C.

TABLE 9. *Logarithms for reduction of volumes to* 0° *C. and* 760 *millimeters pressure.* $(1/1+0.00367\,t) \times (p/760)$

The table is calculated by adding the logarithm of $p/760$ as found in table 6, page 34. The barometric pressure p in this table is the observed reading corrected to 0° C. and t is the observed temperature. No attention is paid to the condition of saturation. The table is used in the reduction to 0° C. and 760 millimeters pressure of volumes of oxygen absorbed, measured with the portable respiration apparatus. The top argument is in millimeters barometric pressure. The side argument is in 0.1° C.

TABLE 10. *Factors for reduction of volumes to* 0° *C. and* 760 *millimeters pressure.* $(1/1+0.00367\,t) \times (p/760)$

The table represents the products of the fraction $1/1+0.00367\,t$, where t equals the temperature, and the fraction $p/760$, where p equals the barometric pressure corrected to 0° C., but uncorrected for pressure of aqueous vapor. The table was actually constructed by finding the antilogarithms of table 9, page 71. It is used for the same purpose as table 9, when calculations are carried out without the use of logarithms.

TABLE 11. *Volumes of oxygen in incoming air corresponding to* 100 *volumes of outgoing air with different percentages of nitrogen.* 79.03 : p. ct. N_2 :: 20.94 : x; where x equals volumes of oxygen in incoming air.

The table is calculated by means of the proportion indicated above, the computation being carried out for all percentages of nitrogen in outgoing air from 78.50 to 80.50 at intervals of 0.01 per cent. The table is used in calculating the oxygen deficit of expired air when the expired air is collected and analyzed for carbon dioxide and oxygen. It is assumed that the inspired air has the same composition as outdoor air, namely, 20.94 per cent oxygen, 79.03 per cent nitrogen, and 0.03 per cent carbon dioxide. The top argument is

from 0.00 to 0.09 per cent by 0.01 intervals. The side argument is from 78.50 to 80.50 by 0.10 intervals.

TABLE 12. *Factors and their logarithms for converting dry gases at 0° C. and 760 millimeters pressure to the observed pressure (corrected to 0° C. for scale correction) and to saturation at 37° C. (body-temperature).* Formula: $760/p-47 \times 310/273 \times$ volume at 0° C. and 760 millimeters pressure.

The table is calculated for each millimeter barometric pressure from 738 to 781 by means of the formula above. The expression $760/p-47$ represents the change from 760 millimeters pressure dry to the prevailing barometric pressure with pressure of aqueous vapor at 37° C. (47 millimeters mercury) subtracted from it, that is, to the pressure of the air in the lungs. The expression 310/273 represents the effect of the change from 0° C. to 37° C. (The temperature of the lungs may not be actually 37° C., but somewhat lower. It is usually assumed that it is 37° C.) The table is useful in calculating the volume per respiration where the total ventilation per minute of the lungs at 0° C. and 760 millimeters pressure dry and the respiration rate are known. The side argument is in millimeters.

TABLE 13. *Calorific values of oxygen and carbon dioxide for non-protein respiratory quotients and proportions of energy from carbohydrates and fat consumed.*

The table is that of Zuntz and Schumburg, Physiologie des Marsches, 1901, p. 361, as elaborated by Williams, Riche and Lusk in the Journal of Biological Chemistry, 12, 1912, p. 357. The logarithms of the calories per liter of oxygen are the logarithms of the factors as they appear in this table. They differ slightly from those in the original table. The values for carbon dioxide are from Benedict and Talbot, Carnegie Institution of Washington, publication 201, 1914, p. 29.

The table is used for calculating the heat derived from carbohydrate and fat when the respiratory exchange is measured. It is the practice of the Nutrition Laboratory to apply the calorific values in this table directly to the respiratory exchange as measured without computing separately the protein metabolized. The side argument is the respiratory quotient in 0.01 intervals.

TABLE 14. *Heat-production per minute, per hour, and per 24 hours, calculated from consumption of oxygen per minute at respiratory quotient 0.82.* (Calorific value of oxygen per liter = 4.825 calories.)

The table is obtained by finding the product of the cubic centimeters per minute, the calorific value of oxygen (4.825), and 1, 60,

and 1,440 and dividing by 1,000. It is useful in deriving the heat-production when only oxygen measurements are obtained, as, for example, with the various portable forms of clinical respiration apparatus.

TABLE 15. *Comparative scales of kilograms and pounds, centimeters and inches.*

This table shows the equivalent scales of kilograms and pounds from about 8 kilograms to 125 kilograms and of centimeters and inches from 80 centimeters to 200 centimeters. Conversion may be made on the scales in either direction and fractional parts estimated. The table is from "The Treatment of Diabetes Mellitus," E. P. Joslin, 1917. The electrotype was furnished through the courtesy of the publishers, Lea & Febiger, Philadelphia.

FORMULAS AND TABLES FOR CALCULATING BODY-SURFACE.

TABLE 16. *Lissauer formula for calculating body-surface of infants and table giving area calculated for weights from 2.00 to 5.00 kilograms.*

The formula for calculating the body-surface of infants is that of Lissauer, where area in square centimeters equals $10.3\sqrt[3]{w^2}$, in which w is equal to the body-weight in grams.

Example of calculation. Body-weight 3,650 grams.

Logarithm of 3650	=	3.56229
		× 2
		3 | 7.12458 log. of w^2
		2.37486 log. of $\sqrt[3]{w^2}$
Logarithm of 10.3	=	1.01284
Logarithm of surface	=	3.38770 = 2,442 square centimeters or 0.2442 square meter.

The table gives the results of this calculation for each 0.05 kilogram from 2.00 to 5.00 kilograms. It is from Benedict and Talbot, Carnegie Institution of Washington, publication 233, 1915, p. 110.

TABLE 17. *Constants for computing surface-area of children from formula*: Area $= K\sqrt[3]{w^2}$.

The table gives the constants to be used for calculating the body-surface of children for weights up to 40 kilograms. The method of calculation is the same as given for the use of the Lissauer formula for infants in table 16. The table is from Benedict and Talbot, Carnegie Institution of Washington, publication 302, 1921, table 14, page 61.

TABLE 18. *Du Bois formula and chart for ascertaining body-surface of men and women.*

The Du Bois formula for calculating the body-surface of adults is $A = Wt.^{0.425} \times Ht.^{0.725} \times 71.84$, where A equals the area in square centimeters, $Wt.$ the weight in kilograms, and $Ht.$ the height in centimeters.

EXAMPLE.

Man, body weight 65.5 kilograms, height 165 centimeters.

Logarithm of $65.5^{0.425}$	$= 1.81624 \times 0.425$	$= 0.77190$
$165^{0.725}$	$= 2.21748 \times 0.725$	$= 1.60767$
71.84		$= 1.85637$
Logarithm of area in square centimeters		$= 4.23594$

Area in square centimeters equals 17,216 or 1.72 square meters.

The chart shows the curves plotted from calculations from various heights and weights. The body-surface may be estimated from the figure. The ordinates are heights in centimeters, the abscissæ are weights in kilograms. The formula and chart are from D. Du Bois and E. F. Du Bois, Archives of Internal Medicine, 17, 1916, p. 865.

C. M. Wilson and D. Wilson have recently published (Lancet, 1920, ii, p. 1042) a "nomogram" which is more convenient for deriving the body-surface from the height and weight by means of the Du Bois formula.

FORMULAS AND TABLES FOR PREDICTING BASAL HEAT-PRODUCTION FOR 24 HOURS.

TABLE 19. *Formula for predicting basal heat-production of new-born infants per 24 hours.*

The formula for predicting the basal heat-production of new-born infants is $h = l$ (length in centimeters) $\times 12.65 \times 0.103 \sqrt[3]{w^2}$. An example of its calculation is as follows: Infant, length, 52 centimeters; body-weight without clothing, 3.63 kilograms.

Logarithm of w (3.630)	$=$	0.55991
		$\times \quad 2$
	3	1.11982
Logarithm of $\sqrt[3]{w^2}$	$=$	0.37327
0.103	$=$	$9.01284—10$
12.65	$=$	1.10209
52	$=$	1.71600
Logarithm of total calories (h)	$=$	2.20420

Heat per 24 hours equals 160 calories.

This formula is applicable up to 8 days of age. It is from Benedict and Talbot, Carnegie Institution of Washington, publication 233, 1915, p. 108.

TABLE 20. *Basal heat-production of boys and girls per 24 hours predicted from body-weight.*

This table gives the basal heat-production of boys and girls for 24 hours as predicted from body-weight without clothing. The values represent points on probable curves drawn through extended series of determinations for which heat has been computed from the respiratory exchange and referred to body-weight. The table is from Benedict and Talbot, Carnegie Institution of Washington, publication 302, 1921, table 36, page 206.

TABLE 21. *Basal heat-production per kilogram per 24 hours predicted from age, for girls from 12 to 17 years of age.*

The table is from Benedict, Hendry, and Baker, Proceedings National Academy of Sciences, 1921, 7, No. 1.

TABLE 22. *Formula for predicting basal heat-production of males per 24 hours.*

The formula for predicting the basal heat-production of males for 24 hours is as follows:

$$h = 66.473 + 13.752\ w + 5.003\ s - 6.755\ a$$

h = heat-production per 24 hours, w = weight in kilograms, s = height in centimeters, a = age in years.

EXAMPLE.

Age 21 years, weight 63.9 kilograms, height 169 centimeters.
$h = 66.473 + (13.752 \times 63.9) + (5.003 \times 169) - (6.755 \times 21) = 1723$ calories.

The formula is from Harris and Benedict, Carnegie Institution of Washington, publication 279, 1919, page 190. Benedict[1] has shown that it is applicable to boys back to 10 kilograms in weight.

TABLE 23. *Formula for predicting basal heat-production per 24 hours for women.*

The formula is: $h = 655.096 + 9.563w + 1.850s - 4.676a$. h = heat-production per 24 hours, w = weight in kilograms, s = stature in centimeters, and a = age in years.

EXAMPLE.

Age 52 years, weight 37.4 kilograms, height 155 centimeters.
$h = 655.096 + (9.563 \times 37.4) + (1.850 \times 155) - (4.676 \times 52) = 1056$ calories.

The formula is from Harris and Benedict, Carnegie Institution of Washington, publication 279, 1919, page 190.

TABLES 24 and 25. *Standard multiple-prediction tables for normal basal heat-production of men per 24 hours.*

These two tables are used together for predicting the most probable basal heat-production per 24 hours of a normal man when the stature in centimeters, the weight in kilograms, and the age in years are

[1] Benedict, Proceedings of National Academy of Sciences, **6**, 1920, p. 9.

known. They are derived from the application of the formula given in table 22. In table 24 the constant term (66.473) and the corrective term for body-weight ($13.752w$) are combined, while in table 25 the corrective term for stature ($5.003s$) and the corrective term for age ($-6.755a$) are combined.

The tables are from Harris and Benedict, Carnegie Institution of Washington, publication 279, 1919, pp. 253–259.

EXAMPLE.

A man 27 years old, 172 centimeters in stature, 77.2 kilograms in weight. From table 24, 77 on side argument and 0.2 on top argument, we find 1128, and from table 25, 27 in top argument and 172 in side argument, we find 678 calories; 1128 + 678 = 1806 calories is the predicted heat.

TABLES 26 and 27. *Standard multiple-prediction tables for normal basal heat-production of women.*

These two tables together are used for predicting the most probable basal heat-production per 24 hours of a normal adult female when the weight in kilograms, the stature in centimeters, and the age in years are known. They are derived from the application of the formula given in table 23. In table 26 the constant term (655.096) and the corrective term for weight ($9.563w$) are combined. In table 27 the corrective term for stature ($1.850s$) and the corrective term for age ($-4.676a$) are combined. The tables are from Harris and Benedict, Carnegie Institution of Washington, publication 279, 1919, pp. 260–266.

EXAMPLE.

A woman 66 years old, 162 centimeters in stature, 62.3 kilograms in weight From table 26, 62 on side argument and 0.3 on top argument, we find 1,251 calories, and from table 27, 66 in top argument and 162 in side argument, we find -9; $1251-9=1{,}242$ calories is the predicted basal heat-production per 24 hours.

TABLE 28. *Calories per square meter of body-surface (height-weight formula) per hour, Aub and Du Bois standards.*

The table gives the heat-production per hour on the basis of body-surface as estimated from height and weight without clothing (see table 18, p. 108). The standards are from Aub and Du Bois, Archives of Internal Medicine, 19, 1917, p. 831. It should be stated that the authors considered the values somewhat tentative and point out that the figures for females are calculated as 7 per cent below the average for males.

TABLE 29. *Formulas for predicting basal metabolism of males and females* (Dreyer).

The formula for males is $C = \frac{\sqrt[2]{W}}{0.1015 \times A^{0.1333}}$, where C equals total calories per 24 hours, W equals body-weight in grams, and A equals age in years. It is from G. Dreyer, Lancet, 1920, Part 2, p. 290.

EXAMPLE.

Subject, 69 kilograms, 20 years.

(1)	Logarithm of W (69000)	$=2)$	4.83885
(2)	$\sqrt{W}$	$=$	2.41943
(3)	$A \times 0.1333$	$=$	0.17343
(4)	0.1015	$=$	9.00647−10
(5)	Sum of (3) and (4)	$=$	9.17990−10
	Subtracting (5) from (2)	$=$	3.23953
	Calories per 24 hours		1736.

The formula for females is $C = \frac{\sqrt[3]{W}}{0.1125 \times A^{0.1333}}$

The terms and the method of use are the same as with the males.

TABLES 30 TO 33.

The tables give equivalents of various units of gases, energy, work, and measures which find use in calculations of respiratory exchange and transformations of energy. The equivalents are given to the same number of significant figures as the sources from which they are obtained, but in most biological work it is seldom necessary to use more than three significant figures.

TABLES, FACTORS, AND FORMULAS.

TABLE 1.

Conversion of seconds to decimal parts of a minute.[1]

Seconds.	Fraction of minute.	Seconds.	Fraction of minute.	Seconds.	Fraction of minute.
1	0.02	21	0.35	41	0.68
2	.03	22	.37	42	.70
3	.05	23	.38	43	.72
4	.07	24	.40	44	.73
5	.08	25	.42	45	.75
6	.10	26	.43	46	.77
7	.12	27	.45	47	.78
8	.13	28	.47	48	.80
9	.15	29	.48	49	.82
10	.17	30	.50	50	.83
11	.18	31	.52	51	.85
12	.20	32	.53	52	.87
13	.22	33	.55	53	.88
14	.23	34	.57	54	.90
15	.25	35	.58	55	.92
16	.27	36	.60	56	.93

TABLE 7.

Logarithms for reduction of saturated volumes to 0° C. dry and 760 mm. pressure. $\left(\frac{1}{1+0.00367\,t} \times \frac{p-e}{760}\right)$; t = temperature; p = barometric pressure corrected for scale correction; e = pressure of aqueous vapor at t.

Temp. °C.	Barometric pressure in millimeters.

TABLE 10.

Factors for reduction of volumes to 0° C. and 760 mm. pressure $\left(\frac{1}{1+0.00367\,t} \times \frac{p}{760}\right)$;
t = temperature, p = barometric pressure corrected for scale correction.

Temp. °C.	Barometric pressure in millimeters.									
	741	742	743	744	745	746	747	748	749	750
10.1	0.940	0.941	0.943	0.944	0.945	0.947	0.948	0.949	0.950	0.952

TABLE 12.

Factors and their logarithms for converting dry gases at 0° C. and 760 millimeters pressure to the observed pressure p (corrected to 0° C. for scale correction) and to saturation at 37° C. (body-temperature).

Formula = $\frac{760}{p-47} \times \frac{310}{273} \times$ vol. at 0° C. and 760 millimeters pressure.

Pressure, p.	Factor.	Logarithm of factor.	Pressure, p.	Factor.	Logarithm of factor.	Pressure, p.	Factor.	Logarithm of factor.

NOTE: This table is for obtaining the volume per respiration. To use it, multiply the reduced ventilation per minute by the factor for p (p = observed barometric pressure corrected to 0° C. for scale correction, but not for tension of aqueous vapor) and divide by the respiration rate. The result will be volume per respiration in liters. (If body-temperature is taken as 34° C., the factor will be lowered about 1 per cent.)

TABLE 13.

Calorific values of oxygen and carbon dioxide for non-protein respiratory quotients and proportions of energy from carbohydrate and fat consumed.

Non-protein respiratory quotient.	Calories per liter of O_2.[1]		Calories per liter of CO_2.[2]		Proportion of calories from—

16½	21.7
17	21.2

TABLE 22.

Formula for predicting basal heat-production of males per 24 hours.

$$h = 66.473 + 13.752w + 5.003s - 6.755a$$

h = heat-production per 24 hours.
w = weight in kilograms.
s = stature in centimeters.
a = age in years.

TABLE 23.

Formula for predicting basal heat-production per 24 hours for women.

$$h = 655.096 + 9.563w + 1.850s - 4.676a.$$

h = heat-production per 24 hours.
w = weight in kilograms.
s = stature in centimeters.
a = age in years.

TABLE 28.

Calories per square meter of body-surface (height-weight formula) per hour, Aub and Du Bois standards.

Age, years	Males	Females
14 to 16	46.0	43.0
16 18	43.0	40.0
18 20	41.0	38.0
20 30	39.5	37.0
30 40	39.5	36.5
40 50	38.5	36.0
50 60	37.5	35.0
60 70	36.5	34.0
70 80	35.5	33.0

TABLE 29.

Formulas for predicting basal metabolism of males and females. (Dreyer.)

Males:

$$C = \frac{\sqrt[2]{W}}{0.1015 \times A^{0.1333}}$$

C = calories per 24 hours.
W = body-weight in grams.
A = age in years.

Females:

$$C = \frac{\sqrt[2]{W}}{0.1125 \times A^{0.1333}}$$

C = calories per 24 hours.
W = body-weight in grams.
A = age in years.

TABLE 30.

Weights of gases at 0° C. and 760 mm. pressure, at sea-level and 45° latitude, and their equivalent volumes.

	Remarks.
1 liter of oxygen = 1.4292 grams	Landolt-Bornstein, Physikalisch-chemische Tabellen, Berlin, 1905, p. 222.
1 liter of carbon dioxid = 1.9652 grams	Do.
1 liter of nitrogen = 1.2542 grams	Do.
1 liter of air = 1.2928 grams	Ibid, p. 11.
1 liter of water vapor = 0.8132 gram	Reciprocal value of volume equivalent to 1 gram.
1 liter of hydrogen = 0.09004 gram	Landolt-Bornstein, Physikalisch-chemische Tabellen, Berlin, 1905, p. 222.
1 gram of oxygen = 0.6997 liter	Reciprocal value of weight per liter.
1 gram of carbon dioxid = 0.5089 liter	Do.
1 gram of water vapor = 1.2440 liters	Calculated on the assumption that a gram molecule of water vapor occupies 22.412 liters at 0° C. and 760 mm., i. e., it acts as a perfect gas.

TABLE 31.

Equivalents of units of energy.[1] ($g = 980.5$)

	Ergs	Kilojoules[4]	Gram meter	Kilogram meter	Foot-pounds	cal. 18° C.	Cal. 18° C.
1 Kilojoule	10^{10}		101989		738.1	239.1	0.2391
1 gram-meter	980.5×10^2	$980.5 \div 10^8$		0.001	0.007236	0.002344	$0.2344 \div 10^5$
1 kilogram-meter	980.5×10^5	$980.5 \div 10^5$	1000		7.236	2.344	0.002344
1 foot-pound	135.5×10^5	$135.5 \div 10^5$	138.2	0.1382		0.3239	0.000324
1 cal.[2] 18°	4.183×10^7	0.004183	426.6	0.4266	3.087		0.001
1 Cal.[3] 18°	4.183×10^{10}	4.183	426600	426.6	3087	1000

[4] Smithsonian Physical Tables, 1920, p. 197, table 212, gives 4.184 joules as "best" value for 1 gram calorie (20° C.). ($g = 980.7$)

TABLE 32.

Equivalents of power, work, and energy. ($g = 981$ centimeters per second per second.)

1 horse power = 745.956 watts.[2]
1 horse power = 4562.42 kilogrammeters per minute.[1]
1 horse power = 33,000 foot-pounds per minute.[1]
1 watt = 0.1019 kilogrammeter per second.
1 watt = 0.737308 foot-pound per second.[2]
1 watt = 1 joule per second = 10,000,000 ergs per sec.
1 British thermal unit per second = 1055 watts.[4]
1 British thermal unit = 778 foot-pounds.[4]
1 gram calorie per second = 4.187 watts.
1 kilogrammeter per second = 9.81 watts.[2]
1 British thermal unit = 0.251996 kilogram calorie.[3]
1 watt-second = 0.2388 gram-calorie.

TABLE 33.

Miscellaneous equivalents.

1 meter = 39.3700 inches.[1]
1 meter = 3.28083 feet.[1]
1 kilometer = 0.62137 mile.[1]
1 mile = 1609.35 meters.[2]
1 inch = 25.4001 millimeters.[2]
1 cubic foot = 28.317 liters.[3]
= 1728 cubic inches.[2]
= 0.028317 cubic meter.[3]
1 cubic inch = 16.387 cubic centimeters.[2]
1 ounce avoirdupois = 28.3495 grams.[2]
1 pound = 453.59 grams.[2]
1 quart (U. S.) = 0.94636 liter.[3]
1 liter = 1.05668 quart (U. S.).[4]
1 mile per hour = 26.822 meters per minute.
1 meter per minute = .03728 mile per hour.
